Hard carbon has been regarded as the most promising anode material for sodium-ion batteries (SIBs) due to its low cost, high reversible capacity, and low working potential.

Li-rich manganese based oxides (LRMOs) are considered an attractive high-capacity cathode for advanced Li-ion batteries; however, their poor cyclability and gradual voltage fading have hindered their practical applications. Herein, an efficient and facile strategy is proposed to stabilize the lattice structure of LRMOs by surface modification of polyacrylic acid (PAA).

Electrolytes as an important part of sodium-ion batteries have a pivotal role for capacity, rate, and durability of electrode materials. On account of the high reduction activity of sodium metal with organic solvents, it is very important to optimize the electrolyte component to realize high stability on Na metal and hard carbon anodes. Herein, chemical and electrochemical stability of ...

Advanced electrolytes play a key role in the development of next-generation lithium secondary batteries. However, many strong polar solvents, as a major component of the electrolyte, are incompatible with the commercialized graphite anode in Li-ion batteries. In this work, we propose a new concept of the coordination number (CN) rule to tune electrochemical compatibility of ...
