Charging of energy storage capacitor

The final charge placed on a capacitor experiences ($\Delta V = V$), since the capacitor now has its full voltage (V) on it. The average voltage on the capacitor during the charging process is ($V/2$), and so the average voltage experienced by the full charge (q) is ($V/2$). Thus the energy stored in a capacitor, (E_{cap}), is

Also, because capacitors store the energy of the electrons in the form of an electrical charge on the plates the larger the plates and/or smaller their separation the greater will be the charge that the capacitor holds for any given voltage across its plates. In other words, larger plates, smaller distance, more capacitance.

Supercapacitors also known as ultracapacitors (UCs) or electrochemical capacitors (ECs) store charge through the special separation of ionic and electronic charges at electrode/electrolyte interface with the formation of electric double layer (electric double layer capacitors to be precise) where charges are separated at nanoscale ($d_{edl} \sim 1 - 2 \text{ nm}$).
