The stored energy is $\frac{1}{2}LI^2$; where L is the coil's inductance (number of turns, core size, core material, etc.). Because energy goes as current squared, doubling the current creates four times more energy. The primary coil's stored energy will become the totality of the spark energy, so it needs to be maximized by increasing the current.

The laminar burning velocity of hydrogen mixtures, listed in Table 2 and illustrated in Fig. 1 over a range of air-to-fuel equivalence ratio, marks out another feature making hydrogen quite different from more common fuels. Around stoichiometry, hydrogen burns over 5 times faster than methane and iso-octane, and a ($\lambda = 2$) hydrogen flame still burns ...
